I would appreciate some help regarding reshaping of the variables b16_01 to b16_20 (from individual datasets) so that I have one variable that I can compare with hv112 (from PR file), for mothers reported to be on the household schedule and whose children are younger than 18 years. I have followed a few examples but not getting it right.

Rather than reshaping the data, have you tried using the BR or the KR files which are already reshaped.

Thank you, the BR file works for me.
