Dear DHS, I am working in a project looking at health system performance for HTN in low- and middle- income countries. We have accessed the 2012 Peru DHS data but have a few questions regarding sample selection and hypertension measurements:

- Eligibility criteria for survey participation (the report states that only women ages 15-49 were interviewed but the sample includes both women and men ages 40-96 years)
- Eligibility criteria for BP measurements (were BP measurements done on all people interviewed or only a subset?) If only a subset, how was this selected?
- Were households revisited if no one was there and/or not all eligible household members were present at the time
- How were BP measurements done? How many measurements and how many minutes in between each reading?

Thank you very much

Dear User, after looking at the final report and the questionnaire I found the following:

- only adults between the age of 40-96 years were eligible for blood pressure measurement
 - This data was only collected in the Household
 - Households for this survey were revisited up 4 times if no respondents at home
 - From the questionnaire, it appears there were two readings for blood pressure recorded
 - From looking at the frequencies, I looked at SH220 "Presión sistólica". The S in SH indicates it's a survey specific variable, the H in SH indicates a Household variable.
-
