Update: I found that in Household questionnaire, for example in dataset for Burkina Faso 2010, there are variables ha63\_01-...-ha63\_18 describing whether the blood was taken or not. Nevertheless, if I compare the data with the dataset containing only HIV/AIDS tests result, I come to completely different numbers, as the HIV/AIDS results dataset contains over 15,000 observations whereas if I sum all the Blood Taken observations, I get only approx. 8,500 observations. Can somebody explain what am I missing here? many thanks
