Thank you for your answer,

concerning DHS 2012 (household survey) could you please explain more in detail how the stratification was conducted?

There are 10 districts, the metropolitan area, and the camps. In the Appendix of the report it is specified that 26 strata were identified: rural and urban for each district and the six municipalities for the metropolitan area.

My questions are:

- a) how can I build a strata variable as above, if I do not have any variable distinguishing SDEs extracted from each of the 6 metropolitan municipalities?
- b) how were the camps considered? From page 355 of the report it looks like that they are a separate "domaine d'échantillonnage". Did you also distinguish camps along the urban/rural dimension?

Thank you,

Andrea
