Subject: Any way to use GSEM with survey data?

---

Hello,  
I'm using Stata/SE 13.1 and working with DHS Nigeria survey data.

I have one outcome variable which is binary (lifetime experience of intimate partner violence: Yes/No). I have 20 predictor variables (14 binary, 5 categorical and 1 latent variable)

I'm trying to prove that 2 of my predictor variables 'marital status' (.i.e. ever married versus never married) and 'age at first marriage' (10-14years, 15-17 years, 18-21 years, 22-46years) have the greatest effects on the outcome - 'lifetime experience of intimate partner violence' (Yes/No).

The Stata manual states that survey data is only supported by SEM. However, apart from this detail, everything else I need for my analysis is supported better by GSEM.

My understanding is that not using survey weights would bias my variance estimates but should not be that much of a problem for my point estimates.

Given what I'm trying to prove here, am I wrong in thinking that biased variance estimates should not be too much of an issue in this instance?

If I am wrong, and using GSEM would lead me to make erroneous conclusions, then is there any way at all to get around this?

Thanks in advance.
