Following is a response from Senior DHS Stata Specialist, Tom Pullum:

You are apparently using the IR files from these surveys. It could be easier to use the PR files. For example, if you go to the PR file for the Egypt 1992-93 survey, EGPR21FL.dta, you have sex (hv104), age in single years (hv105), level of schooling (hv106), and single years of schooling (hv108). This file includes all women, men, and children in the household sample. You can use the weight variable (hv005) to get the distributions you want. The restriction to ever-married women only affects the IR file. You could use that file, with weights v005*awfacte (awfacte, not awfactu), but that would not be as accurate or as easy as using the PR file.
