I wrote a few comments on the program for estimating mortality of children ending with a suggestion of adding two additional conditions.

I noticed 2 technical comments on the child mortality estimation from the SPSS program

- First, there are truncature for the 0 segment in the file tmp2 (deaths) and exposd12 (exposure), then in principle of the CMC based on the months of age, this age interval can't go through a period;

- Then, the principle of exclusion at the limit of the periods is not uniform given that the segments are unequal in length. These observations are noted in more detail in the attached file.

Waiting for your comments and observations, best regards.
