Thanks again.

But i am still a little unclear about one thing.

So when we use svy, we are not only implementing weighting but also taking in to account the sampling design/ the stratification.

But, as you suggest let us say i manually implement the regression using for example xtreg or regxfe by applying the new weight ( constructed to take in to account the three round surveys i used) and clustering at region level.

should i still be concerned about the sampling design/ the stratification?

Best,
