I would like some advise on this:

If I were to run regression analyses for unmet need, would it be best to do logistic regression, making the dependent variable binary by excluding all women who are not at risk for pregnancy (i.e. unmarried or not living with a partner, not sexually active, infecund, etc) or to run multivariate logistic regression with the dependent variable having three outcomes - unmet need, met need and no met need (including the women who are not at risk for pregnancy or who do not have unmet need)?
