Hello again,

I am also using the household members recode by pooling the surveys conducted in different periods. And in this case i have to de-normalize the weight by using the following procedure :

$HV005^* = HV005 \times (\text{total number of residential households in the country at the time of the survey}) / (\text{total number of households interviewed in the survey})$

Unlike, the population of female 15 -49 data that can be obtained from UN, i do not know how to get data on "total number of residential households in the country at the time of the survey".

any help please...

Best,

---
