HW70 is the height-for-age z-score based on WHO standards, although the DHS provides the values times 100 (so HW=100 would be HAZ of 1).

Stunted is defined as more than 2sd below the cutoff, which is -200 in the DHS coding (a "1" on the WHO scale means 1 standard deviation (sd)).

To define stunted children (using Stata syntax).

```
Gen stunted = hw70<-200
```

```
gen severely_stunted = hw70<-300
```

You may have to trim off the values of HAZ that are above/below +/-600 as that is the "valid" range of values (I can't remember if DHS already cuts them). But that is the general idea - you just have to define an indicator variable that takes the value of 1 for children with HAZ below -200 (-2 in WHO speak) and 0 for children with HAZ above that cutoff.
