We are trying to find prevalence of IPV in Couples Data (CR dataset) in India from 2005 and 2015 dataset.
We used D005 (domestic violence weight) and divided by 1000000. When we ran the analyses, the number of weighted observations was SMALLER than the number of observations (unweighted).
In order to generate nationally represented estimate for IPV, what do we do for D005? Do we still divide it by 1 million or smaller number?

Thank you,
Jasmin
