Dear DHS specialist,

I am working on a thesis on the topic of teenage pregnancy and I use multilevel analysis. The data that I use is Indonesian data for 2017.

I want to make a variable of poverty level and education level of women at the community/cluster level. All I know from DHS forum these variables can be created by aggregating individual values into community/cluster values. My question is what variable is the best to use?

- 1. For community education/cluster level variables is it appropriate to use v106?
- 2. For the community/cluster poverty variable, which variable i should use V190 or v191?

Could You kindly help me.

Best regards,

FajarSan
