Yes, initially I was suspecting this possibility as well. By dropping and including various combinations of variables, I realized that my interaction terms were creating such combinations of empty cells. However, I wanted to retain the interaction terms and was looking for alternatives. Stata Tech Support directed me to the weight precision issue. I have suggested a possible alternate model specification in my previous post. If you deem feasible please share the approach your team person adopted to resolve the issue. By doing so, the forum users will have both the alternatives available if anyone encounters similar issue. Thank you.
