
Subject: How to match women to their husbands

I am working on the topic "parental attitudes towards condom education for young children for Myanmar DHS 2015-2016" and two of independent variables are "gender of child" and "age of eldest child" . However, age of eldest child is only available in women dataset in birth history. So, I want to identify the father and match his eldest child age by matching with women data. Please give me advice on this. Thank you so much.
