So actually "group" helps us to distinguish the (different) designs of the surveys, but I would still say that I cluster standard errors at PSU-level/obtain PSU-level robust standard errors?

I guess that this is something I would always have to include.

So when I would like to cluster standard errors at district-level, I first run "egen district\_id = group(district survey)" and then "reg y x, cluster(district\_ID)"?

Thanks a lot!
