I have calculated the perinatal MR using the IR file as guided in the above syntax.  
I found different observations in the original IR file and the resulted calculation.

In the original IR file, was 12,607 and in the resulted file to calculate PNMR was 7,200.

- What makes a significant difference in the number of observations between the two files? Is that because of the criteria included in PNMR only pregnancy 7 months above? Or any other rationale?
- I also find observations in the BR file was 28,682. What causes a significant difference in the number of observations between the IR file and BR file

Best wishes  
Sam
