Hi members,

Just a silly question, perhaps.
Am I able to estimate the effect of X policy on infant mortality rate or on under-five mortality rate relying on pooled KR files across surveys (4 rounds)?
2 rounds are before the policy and 2 are after the policy, so I just want to look at if that reduces such outcomes. infant or under-five mortality rate is just a single number in each survey and I am not sure if that is possible to conduct differences in difference estimation "reg rate Xolicy [iw=weight], robust.

I would be grateful if anyone of reply!
regards
