Thanks a lot, but I have been struggling to understand, how to use "weight that was described".

In order to create an interpolated surface, I only need the proportion of diarrhea for each cluster; as based on the diarrhea proportion one would create an interpolated surface using geostatistical methods. What I am struggling with is how to incorporate 'weight' and assign it to each cluster's diarrhea proportion please?

Could you kindly help with Stata code to do this i.e. how to calculate weighted proportion for each cluster please?

Thank you so much!
