Hi,

I'm currently trying to see the causal relationship between siblings' sex and life outcomes (educational attainment, marital status).

I see that IR contains all the variables i need (MM1,V106,V501). However this datasets is just for women

In Men MR data, there is just life outcomes variables but not siblings' sex variable.

Should I merge MR with IR and if so how with using stata or is there other alternative to get siblings' sex variable for men?
