Dear Stata forum users and experts

I am doing data analysis using the Kenya DHS dataset and have encountered an error while cross-tabulating the number of clusters and the outcome variable to determine the number of participants in each cluster. The Stata output gave me an error message stating "too many values". I used the following commands:

1. First, I created a weight variable.
2. Then, I ran "tab v001 outcome [iw=wt]".

Could you please assist me with resolving this issue?

Thank you so much!
