India

National Family Health Survey - 5

Hi

I am planning to fit a multilevel level consistent with the data hierarchy of the NFHS-5 survey in India. As far as I can understand, the sampling hierarchy was districts - clusters - households - individual participants. Keeping aside the stratification for now. I have the individual and household weights from various files. Is there a source for the cluster level weights to use in the analysis? I have been reading about cluster weights and the posts range over a decade. Not sure if I ran into the most updated post. Has there been any recent update on cluster weights or do we not have sufficient data to calculate these. Any suggestion will be greatly appreciated.

Best
Rakesh
