Hi

we have been working with dhs data in many countries, and we managed to correct for the oversampling and weights. However, we tried to do the same for India (standard dhs 2005-2006, household level). However, in India psu(hv021) uau (hv004) to correct for oversampling. The report suggests that the sampling strategy was the same than for other countries.

-is that correct? if yes is there another way to correct for oversampling?

-if not? how is sampling strategy different? and how to i best take it into account for my statistics?

Thanks a lot!
