Hi

Thank you for doing this.

I am using STATA to analyze the relationship between wealth quintiles and DPT3 vaccination in 8 different countries, DHS V and VI.

After I have declared my survey design for analysis, some of the strata had a single sampling unit, and as a result there are no standard errors reported during my regression analysis. How do I correct that? I asked STATA to treat single units as certainty units which seemed to work but I do not know if that is correct considering the survey design.

2. I do not know if you will cover this but..What is the method for variance estimation? Were there FPC or post-stratification used?

Thank you very much again.
