I am trying to analyse first births in Bangladesh 2011 DHS of ever married women

When I apply the All Women Factor in SPSS it increases both the numerator (eg total number of children ever born) as well as the denominator, giving incorrect percentages.

From other posts I see that I need to do numerator and denominator separately and some examples are given in STATA, but I do not know how to do this in SPSS (I have never used complex sample function) . Can you advise how to do this?

As a first step I am trying to reproduce table 5.9 in the Bangladesh 2011 report Percentage of all women who gave birth by exact age, percentage who have never given birth, and median age at first birth (looking at 20-24).

Many thanks
