Hi,

I have used the child recode (KR) data file for Bangladesh (2011 DHS) in one of my papers. The statistical analysis uses the stata "SVY" command to account for survey design and sampling weights to report the unbiased regression coefficients and the appropriate linearized standard errors. We recently got a request to do some additional regressions that are not supported by the svy command. In that case, will it be fine to conduct these additional regressions using the sample weight (v005) (i.e. pweight=v005) and clustering the standard error by primary sample units?

I would really appreciate your help.

Many thanks
Bibhu
