---

Hi,

I am trying to analyse first births among women aged 20-24, using surveys that use only ever-married women samples. However, I am a little confused as to how to go about using the all women factor. I've searched the forum to find an answer, and have come across a solution that is provided for SPSS, so I know that the denominator and the numerator have to be treated separately, but I'm not sure how to adjust for this using stata and in particular what happens when looking at only a sub-group (those aged 20-24). I am not using data for a specific country right now, but for the sake of working this out, let's say I am using Bangladesh 2011.

Any help would be appreciated. Many thanks.
