Hi,

I ran a survey where each respondent answered 18 questions. I have it in excel so that each 18 rows of data describes the responses of 1 person (which is what I want). As I put the first column as the 'Response_ID', is it important to have all 18 questions associated with the same person with the same 'response ID', or is it better that each row has a different response ID despite being the same person? (When importing into Stata) thanks.

On my understanding of IDs making.

IDs are important to produce to identify respondents of questionnaire modules.

For each person the ID remains same in respondent ID column but for multiple questions the name of variable are mostly differentiated by putting \$ symbol and then option number.

According to your description, forate of your data file seems verticle. But f=generally these are in horizontal formate.

If your explain more on your research question, i may be able to assist you better.

Regards.
