I am trying to check the effect of sanitation on child stunting, wasting and underweight. I want to get some information that what variables of stunting should i take and how should i combine that sanitation variable as my Y variable or if i take water & sanitation both which type of IV will satisfy both variables?

2nd i need to find an IV also so which variables can i take as possible IV.

Moreover, how can i calculate average of sanitation at each community/district level, excluding the household in that particular area?? may be as possible IV. i need stata code for that?

Detailed response is needed please

Following is a response from DHS Research & Data Analysis Director, Tom Pullum:

The DHS staff cannot help you. Perhaps other users will volunteer.
