Subject: Community level Poverty
Posted by saifulhaq on Tue, 27 Jul 2021 08:36:45 GMT

Dear expoerts,
Please give your feedback on the following coding which i have used for constructing "community level poverty" using dhs data of Pakistan. i need to know if this variable has been constructed correctly.

```
gen cpvt=0
replace cpvt=1 if v190==1
bysor v001:egen cmpov=mean(cpvt)
xtile compov=cmpov,nq(3)
la def compov 1 low 2 moderate 3 high
la var compov "Community Poverty Level"
la val compov compov
tab compov[iweight=wgt]
```

Following is a response from DHS Research & Data Analysis Director, Tom Pullum:

It would help if you would say what you intended to do. Otherwise, all we can say is what it appears that you did. You constructed a variable cmpov that has 3 categories, which are terciles based on the proportion of women in the cluster who are in the bottom wealth quintile. The categories are correctly labeled. There are many alternative ways in which you could define a similar measure, but this way of doing it appears to be coded correctly in Stata.

Thank you for your feedback. I am actually trying to generate community level variable using the individual level categorical variable as given in the DHS data set. My next question is regarding the validity of this particular method of constructing community level variable. More precisely, can we take mean of categorical variable while constructing community level variable using a category (lowest quintile for poverty in this case).
Looking forward

Saif

Following is a response from DHS Research & Data Analysis Director, Tom Pullum:

Last year we produced a report that's related to what you are doing
(https://www.dhsprogram.com/pubs/pdf/AS76/AS76.pdf). It uses more than just the bottom
quintile. I think your index is valid and would be useful, but there are alternatives. In my
experience it's hard to interpret the results of a multi-level model with a categorical variable at the
cluster level. Another option would be a continuous cluster-level measure of wealth, such as
simply the percentage of women (or households) that are in the bottom quintile or in the bottom
two quintiles.

Dear Sir,
Thank you for your response. However i would appreciate if you guide me on how to construct
"continuous cluster-level measure of wealth" in stata.

Thanks in advance

Saif

Following is a response from DHS Research & Data Analysis Director, Tom Pullum:

If you just use "cmpov" in the Stata code you sent, rather than "compov", you will have the
proportion of women in the cluster who are in wealth quintile 1. You could treat that as a
continuous measure.

As a slight modification, you could replace "if v190==1" with "if v190==1 | v190==2". This would

---

give the proportion of women who are in wealth quintiles 1 and 2, and I think will be in a better range.

If you multiply by 100, you will have a percentage rather than a proportion.
