Dear all,

I am having trouble to reach the published result of 80.1% coverage for full immunization coverage (basic antigens, either source) in children aged 12-23 months in Kenya 2022 survey.

I have calculated each individual vaccine coverage (BCG, three doses of DPT-HepB-Hib, three doses of polio vaccine excluding polio vaccine given at birth, and one dose of MR) and the results match with the published report, with less than 0.7 pp difference.

However, when I calculate the full immunization indicator I found a 69.5% coverage, which is 10.6 pp lower from the published result.

I am wondering if there is something different in the definition of full immunization indicator. Can you help me with that.

Thanks in advance.

Following is a response from DHS staff member, Tom Pullum:

The calculation of the immunization rates is complex because of a distinction between whether the information comes from a card or from the mother. There is no simple way to check why you are getting this inconsistency. Please review the Stata code (if you are using Stata) given on our GitHub site: https://github.com/DHSProgram/DHS-Indicators-Stata/blob/master/Chap10_CH/CH_VAC.do
