Hi

I am using EGIR5ADT EGIR61DT, which are 2008 - 2014 IR recode files for Egypt.

I constructed the age gap in STATA by this command

```
gen age_gap= v730. - v012
```

where

v730 husband/partner age

v012 mother age

however, some results that I got are not matched with other variable.

for example, which pasted bellow, A man aged 15 will not be able to have higher education in his age or having 7 children.

Husage: 15

mage: 49

age_gap: -34

nofchildren: 7

wealth: Richest

m_occ: Not employed

hus_occ: Professional, technical or managerial

hedu_years: 15

heducation: Higher education

where

Husage is the husband age

mage is the mother age

nofchildren is number of children under 5 in the HH

m_occ id mother occupation

hus_occ is husband occupation

hedu_years is husband education in years

heducation is husband educational level

This issue found in couple of individuals in the sample and my question here, Is this count as outliers in the dataset and need to be dropped ?

Thank you..

Following is a response from Senior DHS staff member, Tom Pullum:

There are probably data quality issues with the woman's report of her husband's age. In the IR61 file I see that the difference ranges from -34 to +68. It's hard to say what combinations are implausible, because there probably are genuine cases of large age differences, although more likely in a positive rather than negative direction. Your checks for education and children ever born are helpful. You could also look at the MR and CR files EXCEPT THAT Egypt has not included interviews with men, so those files do not exist.

Note that the woman may have had an earlier marriage and there may be other wives (see v505).

I suggest that you categorize the age difference so you have open-ended categories for large negative and large positive differences, and in your analysis you comment on the implausibility of the extreme values. I would NOT recommend that you try to adjust or edit the individual values of the husband's age.
