Dear DHS team,

I'm trying to analyze trends in using different contraceptive methods in Zambia using a calendar module as well as sub-group analysis, such as mean rate of contraceptive methods comparing urban to rural (or teenagers vs adults).

The data structure is like below:

ID month-year condom

1. Jan-2013. 1

1. Feb-2013. 0

1. Mar-2013. 0

.

.

1 Dec-2013. 1

ID

2. Jan-2013. 1

2. Feb-2013. 1

2. Mar-2013. 1

.

.

2 Dec-2013. 1

I want to calculate aggregated rate of using contraceptives each month, and each month has different numbers of observations. (not all individuals followed up for same length of months)

To do this, I used following code:

```
collapse (mean) condom injectable f_sterilization m_sterilization implants iud traditional [pweight = weight] , by(cmc teen )
```

Using these numbers, graphs were produced and I did regression analysis. I think I have to use individual weights but I'm not sure whether I'm doing correctly. Also, if I want to do sub-group analysis by urban vs rural, should I apply individual weights to calculate the aggregated mean by sub-groups?

Thank you!

Following is a response from Senior DHS staff member, Tom Pullum:

Your use of weights within the collapse command is sufficient for the aggregation. For analysis with urban/rural groups you would include v025 in the by() option.

Normally with collapse I use "[iweight=v005/1000000]" but it should be equivalent to what you did. In the aggregation there is no adjustment for the cluster or stratum effects that are part of the full svyset command but for a descriptive analysis that's ok. Weights are the only component of svyset that affect point estimates such as means and rates.
