I have a question about new weights for merged surveys, my idea is to multiply the proportion of each survey to the merged file by the weight of that observation (wt), is this the right thing to do?

This R code is here:

```
data$wt<-data$v005/100000
```

```
survey_counts <- table(data$v000)
```

```
total_samples <- nrow(data)
```

```
survey_proportions <- survey_counts / total_samples
```

```
data$survey_proportion <- survey_proportions[data$v000]
```

Can you give me some advice about this weighting?
