I have a question about new weights for merged surveys, my idea is to multiply the proportion of each survey to the merged file by the weight of that observation (wt), is this the right thing to do?

This R code is here:
```
data$wt<-data$v005/100000
survey_counts <- table(data$v000)
total_samples <- nrow(data)
survey_proportions <- survey_counts / total_samples
data$survey_proportion <- survey_proportions[data$v000]
```

Can you give me some advice about this weighting?

Make sure your calculations reflect the correct proportions, as this can significantly affect the results of your analysis!
