Hi everybody,
I am working on Malawi data. I have merged the data set with HIV test result (AR) with the data set with women information (IR). Now, I would like to create some descriptive tables with both information (like HIV positive with education) but I don't know which weight I have to use because both data sets have their own weight (HIV has one, education has another). I have tried with both weights and the estimates of course are different.

Thank you very much for your help.

Regards
Fabio

Response from Senior Data Processing Specialist, Nouredine Abderrahim:

If you are using the HIV subsample, you need to use the HIV weights. Otherwise, you need to use the women's weight.
