Are state-level sampling errors available for the 2013 Nigerian DHS? While the published reports document National, Urban/Rural, and Regional estimates for the sampling errors they do not go down to the state level.
Thank you!

Following is a response from Senior DHS Sampling Specialist, Ruilin Ren:

It is true that the appendix C (estimation of sampling errors) in the final report of Nigeria DHS 2013 did not provide sampling errors at the state level, because it's a lot of tables.

We do not have the state level sampling errors in house either. However, it is true that the survey was designed to allow break down to state levels, so data users can calculate the sampling errors at the state level if they need to.

Thank you!
So using the SAS proc surveyfreq procedure should work for calculating sampling errors at the state level?

Following is a response from Senior DHS Sampling Specialist, Ruilin Ren:

Yes, you can use the PROC SURVEYFREQ to calculate the sampling errors for simple proportions at the state level. You need to declare the survey parameters such as CLUSTER and STRATUM. I will suggest you use PROC SURVEYMEANS which calculates the sampling errors for means, proportions and ratios.

Hello, I am surprised to read that PROC SURVEYFREQ would calculate the sampling errors
appropriately. Some (or many?) of the country reports have an appendix "ESTIMATES OF
SAMPLING ERRORS" which outlines the complex calculations used to calculate the sampling
errors, including that DHS staff wrote a special program to run a bootstrap to calculate the SEs.
So are you saying that the SAS survey PROCS can replicate that same program?
I apologize for doubting, I just want to be sure I understand correctly.

Please see the following response from our Senior Sampling Statistician, Ruilin Ren:

The SAS PROC SURVEYMEANS can calculate sampling errors for simple indicators such as
means, proportions, and ratios. But it cannot calculate complex rates such as for the TFR, CMR
and MMR. ICF developed SAS codes for the sampling errors presented in appendix B, which
used the PROC SURVEYMEANS for simple indicators. For TFR, CMR and MMR, a special code
was developed using Jackknife. Though the PROC SURVEYFREQ can also calculate sampling
errors for proportions, but it is not used in the ICF's code for sampling errors. You can specify the
variance estimation method in PROC SURVEYMEANS including Bootstrap and Jackknife, but
again it is for simple indicators. ICF codes did not use replicate method for simple indicators.
