Subject: Uganda 2011 domestic violence Posted by mariano.salazar@ki.se on Fri, 22 Sep 2017 13:16:21 GMT View Forum Message <> Reply to Message

Dear editor.

I am using the 2011 Uganda data set to study the association between women's exposure to IPV and HIV testing. I have several questions:

- 1. I am using the svy command in Stata to run the analysis taking int account the survey sampling design; however, key variables about the strata are empty in the survey (V022 V023). These variables are often used to run Svy so what can be done when these are empty.
- . tab V023 no observations
- 2. The variables describing IPV exposures for women are confusing (i.e. D105A-J). For example, when you tab variable D105A (Ever been pushed, shook or had something thrown by husband/partner) you get five options: never, often, sometimes, Yes but not in the last 12 months, Yes but frequency in last 12 months.

How do you interpret this if you ant to create a variable that measures ever exposure to this behavior (yes, no). No must be never, but what about yes. Ever exposure (Yes), should include often, sometimes, Yes but not in the last 12 months or Yes but frequency in last 12 months?

This is an example of my stata dofile

```
generate EverPhy = .

replace EverPhy =1 if (D105A==1)
replace EverPhy =1 if (D105A==2)
replace EverPhy =1 if (D105A==3)
replace EverPhy =1 if (D105A==4)
replace EverPhy =0 if (EverPhy ==.)
```

This is more confusing as the questionnaire the questions are structured in a different way. First is a yes, no question for ever exposure. And then the 12 month exposure to IPV is evaluate uisng the following: often, sometimes, Yes but not in the last 12 months.

when i run my calculations my prevalence does not match the prevalence described in the report.

Can we get the dofile taht describes how the IPV exposure were created for the 2011 DHS report?

3. We are using variable V826A (months ago from recent HIV test) to create a binary variable
