Dear Sir/Madam,

I am working on Armenia AMKR7 datasets, and found that there are two sets of variables for pneumococcal vaccine. These are h54,h55, h56 and s508n1,s508n2,s598n3. I am not sure what is the difference between these sets. For example it is titled both in h54 and s508sn1 as "received pneumococcal 1". But the data are different between them. I don't know which one to use. Could you kindly enlighten me?

In addition, I notice that there is no observation in h37i(children who received oral antibiotics for fever). Is it the case or should I look for that variable somewhere else with different name?

Thank you in advance for your time and kind support.

Your sincerely,
Phyumar
