Hello everyone,

for my research I am trying to measure the shortest distance of each household interviewed in a survey round to the Internet network within that country. I am intending to define a control and treatment group based on the households' distances to the Internet network. Those households in the proximity of 500 m to the network will be part of the treatment group whereas the rest of the households will depict the control group.

I am using QGIS but am not sure which plugin or method to use.

Any help or advice would be highly appreciated.

Thanks a lot in advance,

Marie
